

- ▶ Evolution 2014: basic comparison between NA and European mammal survival
- ▶ GSA 2014: current fully Bayesian model of brachiopod survival
  - ▶ lots of positive feedback, ideas

# Travel and grants

- ▶ AMNH: tooth measures for all notoungulate specimens identified to species level
- ▶ DDIG: applied; travel to Argentina; collaboration with Rick Madden

Death and taxa: time invariant differences in species duration

# North American survival

- ▶ species duration as measure of survival
- ▶ traits
  - ▶ organismal: diet, locomotor categories
  - ▶ species: body size, bioprovince occupancy
- ▶ origination cohort
- ▶ phylogeny primarily based on taxonomy
- ▶ duration defined as number of 2My bins from FAD to LAD, inclusive
- ▶ fully Bayesian hierarchical model
- ▶ censoring approach
  - ▶ if still extant, right censored
  - ▶ if not extant and duration of only 1 bin, left censored

# Censoring

# Modeling censored observations

## Definition

$$S(t|\alpha, \sigma) = \exp\left(-\left(\frac{t}{\sigma}\right)^\alpha\right)$$

Right censored evaluated at  $S(t)$ , left at  $1 - S(t)$ .

Equivalent to ccdf and cdf respectively.

# Modeling censored observations

Likelihood

$$L \propto \prod_{i \in C} \text{Weibull}(y_i | \alpha, \sigma) \prod_{j \in R} S(y_j | \alpha, \sigma) \prod_{k \in L} (1 - S(y_k | \alpha, \sigma))$$

# Posterior predictive checks: $S(t)$

# Posterior predictive checks: deviance residuals

# Posterior predictive checks: point checks

# Pairwise differences of $\beta$ , dietary category

# Pairwise differences of $\beta$ , locomotor category

# Other traits

# Cohort effect

# Variance partition coefficient

- ▶ Because GLMM, VPC approximated via simulation modified from Goldstein *et al.* '02 *Understanding Statistics*
- ▶ phylogenetic heritability, *sensu* Lynch '91 *Am. Nat.*, is a special case of VPC.

# Hazard curvature

# Meaning

## Results

- ▶ model generally fits; no systematic biases in residuals
- ▶ comparable probabilistic statements of trait, temporal, and historical effects
  - ▶ individual level is major source of variance
  - ▶ phylogenetic, cohort effect similar
- ▶ weak decreasing cohort survival risk over Cenozoic
- ▶  $h(t)$  not constant over  $t$ , increases slowly

## Interpretation

- ▶ non-zero temporal and historical effects, but very small
  - ▶ older lineages out-competed by younger (Wagner and Estabrook '14 *PNAS*)
- ▶ increasing extinction with group age (Quental and Marshall '13 *Science*)
- ▶ background extinction; no single mode of extinction
- ▶ relative effect of universality of covariate, levels of selection(?)

A model of biological, spatial, and phylogenetic effects on Cenozoic mammal co-occurrence

# Biogeographic network

## Species adjacency

# Autoregressive model

Adjacency is also a symmetric  $n$  by  $n$  matrix,  $A$ , with ones on the off-diagonals if the species co-occur.

CAR prior. Estimate spatial correlation ( $\rho$ ) and hierarchical variance variance ( $\sigma^2$ ) as a multivariate normal effect with mean vector all 0 and covariance matrix  $= \sigma^2 * (I - \rho * A)$

# Erdos-Renyi graph $G(n, p)$

# Overdispersion model

## Negative Binomial

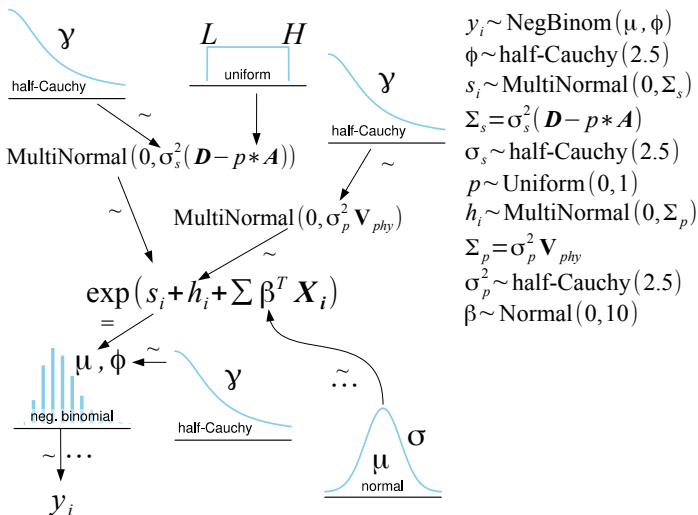

$$\text{NegBinom}(y|\alpha, \beta) = \binom{y + \alpha - 1}{\alpha - 1} \left( \frac{\beta}{\beta + 1} \right)^2 \left( \frac{1}{\beta + 1} \right)^y$$

reparameterized

$$\text{NegBinom}(y|\mu, \phi) = \binom{y + \phi - 1}{y} \left( \frac{\mu}{\mu + \phi} \right)^y \left( \frac{\phi}{\mu + \phi} \right)^\phi$$
